Abstract
An investigation using averaging method is carried out to obtain the frequency response of a class of vibration isolators with saturation spring. The saturation characteristics are modeled using a hyperbolic-tangent function. The hyperbolic-tangent saturation function is compared with other popular saturation functions, using piecewise nonlinear approximation. A parametric study indicates that piecewise linear approximation of saturating functions provide results that are close enough to the results of hyperbolic tangent approximation. A sensitivity analysis of frequency response of the system is also investigated based on the piecewise linear approximation.

1. INTRODUCTION
Figure 1 depicts mechanical model of a one degree-of-freedom suspension system. Recently a new type of damper with a saturation characteristic has been introduced in vibration optimization community. Using Magneto Rheological (MR) fluids and applying an electric current, the damping coefficient of the damper can be controlled almost linearly within a specific range of velocity. However, the force of the damper will be saturated when the velocity approaches a critical value called “breaking velocity” (Jolly 1996), and additional force will be developed when the velocity exceeds the breaking velocity (Jolly et. al. 1996).

Magneto Rheological (MR) and Electro Rheological (ER) fluids also show a saturating stiffness behavior i.e., a saturating spring. Saturating stiffness phenomenon are generally a characteristic occurring in magnetic field and result in enhancement of shear stress developed within the fluid, as well as dry friction dampers. This property is also employed to control the cantilever magnetometry, (Chabota, and Moreland 2003), hydraulic springs (Walsh, and Lamancusa 1992) and electro-mechanical valves actuators (Tai, Stubbs, and Tsao 2001). Also, inclusion of the stick-slip and hysteresis in the model of dry friction law during the slip phase, creates a creep force that saturates at the adhesion limit value. This is a model utilized in the dynamics resulting from the coupling between the nonlinearities in the dry friction model, and the impact with the guidance of railways (True, and Asmund 2002).

In this paper a vibration isolation system employing a nonlinear cubic spring along with a saturation spring in parallel with a linear viscous damper is studied under base excitation. The behavior of such a system can be described by the following equation of motion.

\[ u^{\prime\prime} + a_{1}u^{\prime} + u + a_{2}u^{3} + a_{3} \tanh \left( a_{4}u \right) = r^{2} \sin \left( r \tau \right) \]

The steady state frequency-amplitude dependency of the system is derived by applying the averaging method. The analytical results have been utilized to investigate the parameter sensitivity. The main outcome of this analysis would be comparison of the smooth saturating model with piecewise linear saturating model. Also it will be demonstrated that the piecewise linear model reserves the main dynamic characteristics of the saturating spring phenomenon.
Different analytic functions are available to describe a saturating phenomenon. The most popular functions are illustrated in Figure 2, and are compared to piecewise linear saturating model. The analytic descriptions of the saturating functions are as follow.

a. Hyperbolic-tangent type

\[ F_1(x) = \tanh(bx) \]  

b. Arc-tangent type

\[ F_2(x) = \tan^{-1}(bx) \]  

c. Hyperbolic-cosine type

\[ F_3(x) = a \ln(\cosh(bx)) \]  

The maximum force of the saturating spring and the breaking amplitudes are functions of the control characteristics, which are embedded in parameters \( a \) and \( b \). Experimental investigations show that hyperbolic-tangent describes the behavior of a saturating spring and damper more accurately.

Figure 3 compares the hyperbolic-tangent with its series approximation of different order. It is shown that increasing the order of expansion does not represent the saturation behavior of the function. Hence, instead of a continuous function approach, we employ a piecewise nonlinear function approach.

Using a Taylor series the hyperbolic-tangent function was expanded into a polynomial function.

\[
\tanh(bx) = abx - \frac{1}{3}ab^3x^3 + \frac{2}{15}ab^5x^5 \\
- \frac{17}{315}ab^7x^7 + \frac{62}{2835}ab^9x^9 + O(x^{11})
\]  

(4)

Three different expansion will be utilized to describe the saturating function within the limits of working amplitudes. The first function is found by expanding the hyperbolic-tangent function about \( x=0 \).

\[
f_1 = \tanh(bx)\bigg|_{x=0} = abx - \frac{1}{3}ab^3x^3
\]  

(5)

Two other functions \( f_2 \) and \( f_3 \) may be developed by expansion at two arbitrary positions \( \delta_0 \) and \(-\delta_0\) accepting another third order polynomials. The switching amplitude \( \delta_0 \) may be selected to provide the best curve fitting. Expanded functions \( f_1, f_2, \) and \( f_3 \) are illustrated in
Figure 4. Accepting $f_1$ for $-\delta_0 \leq bx \leq \delta_0$, $f_2$ for $\delta_0 \leq bx < \delta_1$, and $f_3$ for $-\delta_1 < bx \leq -\delta_0$, where $\delta_1=2$ and $\delta_0<1$ is a user defined fixed value, provide a piecewise nonlinear approximation of the saturating function.

$$
atanh(bx) = \begin{cases} 
a & 2 < bx \\
f_2 & \delta_0 \leq bx \leq 2 \\
f_1 & -\delta_0 \leq bx \leq \delta_0 \\
f_3 & -2 \leq bx \leq -\delta_0 \\
-a & bx < -2
\end{cases}
$$  \hspace{1cm} (6)

The approximated piecewise nonlinear function (6) is illustrated in Figure 5 and is compared with the hyperbolic-tangent function. The limit values of $\delta_0$ for switching functions $f_2$, and $f_3$ is selected based on $|atanh(bx) - f_2| < 0.001$, although it could also be found by minimization of the error function $e = |atanh(bx) - f_2|$. Whenever the absolute value of the argument $bx$ passes the limit values then $tanh(bx)$ is assumed to be one.

Assuming a nonlinear third order function for the primary spring, and a linear characteristic for the primary damper, the equation of motion of the system shown in Figure 1 would be:

$$
mx'' + c(x - y) + k_1(x - y) + k_2(x - y)^3 + atanh(b(x - y)) = 0
$$  \hspace{1cm} (7)

Introducing a relative displacement coordinate $z=x-y$, and employing a set of dimensionless parameters, the equation of motion transforms to the following equation, wherein

$$
u'' + a_1u' + u + a_2u^3 + a_3\tanh(a_4u) = r^2 \sin(r\tau)
$$  \hspace{1cm} (8)

where

$$
a_3 = \frac{a}{k_1Y} \quad z = u \quad \omega_i = \sqrt{\frac{k_1}{m}} \quad \omega = \frac{\omega_i}{\omega_i} \quad a_4 = bY
$$

$$
y = Y \sin(\omega t) \quad a_1 = \frac{c}{\sqrt{k_1m}} \quad a_2 = \frac{k_2Y^2}{k_1} \quad x - y = z
$$  \hspace{1cm} (9)

2. FREQUENCY RESPONSE

2.1. Nonlinear Spring, No Saturation

Setting $a_3=0$ in Equation (8), the problem reduces to a base excited Duffing-type vibration isolator.

$$
u'' + a_1u' + u + a_2u^3 = r^2 \sin(r\tau)
$$  \hspace{1cm} (10)

A closed form equation describing the frequency response of the system (10) may be found using a perturbation and
approximation method such as averaging method (Nayfeh and Mook 1979, Tondle 1986).

\[ 9a_2^2U^6 + 24\left(a_1 - a_2^2 r^2\right)U^4 + 16\left(1 + r^4 - 2r^2 + a_1^2 r^2\right)U^2 = 16 r^4 \]  

(11)

Frequency responses of the linear and nonlinear cases with no saturation are plotted in Figure 6 for \(a_1=0.2\) and \(a_2=0.04\). Deviation of the spring from a fixed value and its dependence on the generalized displacement coordinate, introduces new features such as jump phenomenon (Stoker 1955).

\[ u'' + a_1u' + u + a_2u^3 = r^2 \sin(r\tau) \]  

Figure 6: Frequency responses of the linear, and hardening spring for \(a_1=0.2, a_2=0.04\).

2.2. Saturating Spring

The problem discussed in here is a base excited nonlinear vibration isolator with saturating spring with the following equation

\[ u'' + a_1u' + u + a_2u^3 + a_3 \tanh(a_4 u) = r^2 \sin(r\tau) \]  

(12)

In order to investigate the frequency response of the system, we employ the averaging method. Then, we assume a solution in form of

\[ u = U(\tau) \sin(\varphi(\tau)) \]  

(13)

where

\[ u' = U(\tau) r \cos(\varphi(\tau)) \]  

(14)

\[ \varphi(\tau) = r\tau + \psi(\tau) \]  

(15)

Equations (13) and (14) imply

\[ U' \sin \varphi + U \psi' \cos \varphi = 0 \]  

(16)

and

\[ u'' = rU' \cos \varphi - rU (r + \psi') \sin \varphi. \]  

(17)

Substituting Equations (13), (14), and (17), into Equation (12) leads to

\[ r(U' + a_1 U) \cos \varphi + U (1-r\psi') \sin \varphi + a_2 U^3 \sin^3 \varphi \]

\[ + a_4 f(u) = r^2 \sin(\varphi - \psi) \]  

(18)

Solving Equations (16) and (18) for \(U'\) and \(\psi'\), and simplifying, generate the following equations

\[ rU' = (U' (r^2 - 1) \sin \varphi + r^2 \sin(\varphi - \psi)) \cos \varphi \]

\[ - (a_1 U \cos \varphi + a_2 U^3 \sin^3 \varphi + a_4 f) \cos \varphi \]  

(19)

\[ rU \psi' = -(U^2 \sin \varphi - a_1 U \cos \varphi - U' - a_4 f) \sin \varphi \]

\[ - (r^2 \sin(\varphi - \psi) - a_2 U^3 \sin^3 \varphi) \sin \varphi \]  

(20)

The variables \(U'\) and \(\psi'\) are slowly varying with time, and we may assume that their average remain constant over a period of oscillation. Hence,

\[ 2\pi r U' = \int_0^{2\pi} \left[ (U' (r^2 - 1) \sin \varphi + r^2 \sin(\varphi - \psi)) \cos \varphi \right] d\varphi \]

\[ - \int_0^{2\pi} \left[ (a_1 U \cos \varphi + a_2 U^3 \sin^3 \varphi + a_4 f) \cos \varphi \right] d\varphi \]

\[ = -\pi(a_1 U + r \sin \psi) + \int_0^{2\pi} f(U \sin \varphi) \cos \varphi d\varphi \]  

(21)

\[ 2\pi \psi' r = \int_0^{2\pi} \left[ (U - U' \sin \varphi + a_1 U \cos \varphi + a_4 f) \sin \varphi \right] d\varphi \]

\[ + \int_0^{2\pi} \left[ (-r^2 \sin(\varphi - \psi) + a_2 U^3 \sin^3 \varphi) \sin \varphi \right] d\varphi \]

\[ = \frac{\pi}{r} \left( -a_2 U^3 + U (1 - r^2) - r^2 \cos \beta \right) \]

\[ + a_4 \int_0^{2\pi} f(U \sin \varphi) \sin \varphi d\varphi \]  

(22)

where
\[
\begin{align*}
\mathbf{f}(\sin \varphi) = \\
\begin{cases}
\mathbf{f}_1(\sin \varphi) & -\varphi_0 < \varphi < \varphi_0 \\
\mathbf{f}_2(\sin \varphi) & \varphi_0 < \varphi < \varphi_1 \\
\mathbf{a}_3 & \varphi_0 < \varphi < \pi - \varphi_1 \\
\mathbf{f}_3(\sin \varphi) & \pi - \varphi_1 < \varphi < \pi - \varphi_0 \\
\mathbf{a}_3 & \pi - \varphi_1 < \varphi < \pi - \varphi_0 \\
\mathbf{f}_3(\sin \varphi) & 2\pi - \varphi_1 < \varphi < 2\pi - \varphi_0 \\
\end{cases}
\end{align*}
\] 
(23)

and

\[
\begin{align*}
\mathbf{f}_1(x) &= a_4 x - \frac{1}{3} a_4 x^3 \\
\mathbf{f}_2(x) &= \frac{a_4}{Z_2} x^3 Z_{11} + a_4 x^2 Z_{12} + \frac{a_4}{Z_4} x Z_{13} + \frac{a_4}{Z_6} Z_{14} + \frac{a_4}{Z_8} Z_{15} \\
\mathbf{f}_3(x) &= \frac{a_4}{Z_2} x^3 Z_{11} + a_4 x^2 Z_{12} + \frac{a_4}{Z_4} x Z_{13} + \frac{a_4}{Z_6} Z_{14} + \frac{a_4}{Z_8} Z_{15}
\end{align*}
\] 
(24)

Z_7 to Z_10 can be found in Appendix. Also we define

\[
\begin{align*}
\varphi_0 &= \sin^{-1}\left(\frac{\varphi_0}{U}\right), \quad \delta_0 = 0.6 \\
\varphi_1 &= \sin^{-1}\left(\frac{\varphi_1}{U}\right), \quad \delta_1 = 2.0.
\end{align*}
\] 
(25)

At steady state conditions, the left hand side of Equations (21) and (22) should be considered zero. Evaluation of the integrals

\[
\int_0^{2\pi} \mathbf{f}(\sin \varphi) \cos \varphi \, d\varphi, \quad \int_0^{2\pi} \mathbf{f}(\sin \varphi) \sin \varphi \, d\varphi
\] 
(26)

on the right hand side of Equations (21) and (22) must be carried on in three steps.

**Step 1.** In the first step we assume \( U \leq \delta_0 \). Then, \( \varphi_0 \) and \( \varphi_1 \) do not exist, and the saturating spring will never pass the limits of applicability of the principal expanded function about zero. The integrals must be evaluated using \( \mathbf{f} = \mathbf{f}_1 \) for entire the cycle of integration. The solution in the first step is valid as long as \( 0 < U \leq \delta_0 \). Then the results of the averaging method would be

\[
r \sin \psi = -a_1 U
\] 
(27)

**Step 2.** In the second step we assume \( 0 < U \leq \delta_1 \). Then, no \( \varphi_1 \) exist, and the saturating spring will never saturate, but it goes beyond the validity of the principal expanded function about zero. So, the integrals must be evaluated using \( \mathbf{f} = \mathbf{f}_2 \), \( \mathbf{f} = \mathbf{f}_3 \) and \( \mathbf{f} = \mathbf{f}_4 \) in the cycle of integration. The solution in the second step is valid as long as \( \delta_0 < U \leq \delta_1 \). Hence, we have

\[
r \sin \psi = -a_1 U \\
r \cos \psi = -a_1 U \\
\tan(\psi) = \frac{-a_1}{\left(1 - a_1^2 + a_1 \frac{a_3}{U^3}\right) + \frac{1}{4} U^3 \left(3a_2 - a_3 a_4^3\right)}
\] 
(28)

where \( Z_{11}, Z_{12} \) and \( Z_{13} \) can be found in Appendix.

Hence, the frequency response, and phase angle of the motion are

\[
Z_{11}r^4 + Z_{12}r^2 + Z_{13} = 0
\] 
(29)

\[
tan(\psi) = \frac{-a_1}{\left(1 - a_1^2 + a_1 \frac{a_3}{U^3}\right) + \frac{1}{4} U^3 \left(3a_2 - a_3 a_4^3\right)}
\] 
(30)

which can be used to get the implicit equations for the amplitude \( a \), and phase \( \psi \), as functions of the excitation frequency \( r \).

\[
(\pi a_1 r Z_{15} U)^2 + [ -Z_{16} U^3 - Z_{17} U^2 + (\pi Z_{15} (r^2 - 1) - Z_{18} U - Z_{19})^2 = 1
\] 
(31)

\[
tan(\psi) = \frac{\pi a_1 r Z_{15} U}{-Z_{15} U^3 - Z_{16} U^2 + (\pi Z_{15} (r^2 - 1) - Z_{18} U - Z_{19})}
\] 
(32)

\[
Z_{14} to Z_{18} are indicated in the appendix. Equation (36) is the required frequency response function that can be utilized to attain the dimensionless amplitude \( U \) at frequency \( r \), or vice versa.
Step 3. In the third step, we assume $\delta_i < U$. Then, both variables $\varphi_0$ and $\varphi_1$ must be considered, and the integrals must be evaluated using Equation (23). The solution in the third step is valid as long as $\delta_i < U$.

\[
\begin{align*}
    r \sin \psi &= -a_i U \\
    \pi r^2 \cos(\psi) &= \pi (1-r^2) U + 4a_1 \cos(\varphi_1) \\
    + \frac{1}{Z_{19}} (Z_{20} U^3 + Z_{21} U^2 + Z_{22} U + Z_{23}) \
\end{align*}
\]

$Z_{19}$ to $Z_{23}$ are defined in Appendix.

2.3. Piecewise Linear Saturating Spring

In order to evaluate the importance of having a smooth saturating function compared to a simple approximation, in this section we assume a piecewise linear model instead of hyperbolic tangent function. Frequency response analysis of smooth saturating model produces a set of complicated equations. Therefore, we must evaluate the trade off between working with simpler model and the accuracy.

Using piecewise linear approximation, the equation of motion would be

\[
u'' + a_i u' + u + a_2 u^2 + a_3 f(u) = r^2 \sin(r \tau).
\]

where

\[
f(u) = \begin{cases} 
    1 & u > \frac{1}{a_4} \\
    a_4 u & \left|u\right| \leq \frac{1}{a_4} \\
    -1 & u < -\frac{1}{a_4}
\end{cases}
\]

Applying the averaging method will produce the following implicit equations for frequency response and phase of the system.

\[
\begin{align*}
    16 \pi^2 r^2 a_i^2 U^2 - 16 \pi^2 r^4 \\
    + \left(4a_3 a_4 (2\varphi_0 - \sin 2\varphi_0) + \pi (3a_2 U^2 - 4r^2 + 4)\right)^2 U^2 \\
    + \left(+16 a_3 \cos \varphi_0\right)^2 U^2 = 0 \\
    U > \frac{1}{a_4}
\end{align*}
\]

3. RESULTS

Figure 7 depicts the frequency response of the system for different coefficient of the saturating term. The resonance frequency shifts to the higher frequencies by increasing the strength of the saturation. The peak of frequency response also increases by increasing the saturation strength. The effects of the variation of switching amplitude are illustrated in Figure 8.

Further analysis can be examined by comparing analytic equations derived in the previous section. Effect of varying $a_3$ and $a_4$ are illustrated in Figure 10 and 11 respectively.

A sample of the phase angle of the steady state response is depicted in Figure 12, using the piecewise linear model. Nonlinear behavior and jumping phenomenon can be seen clearly.

CONCLUSION

A nonlinear suspension system has been studied, including a cubic restoring force element, a linear viscous damper, and a saturating restoring stiffness. Applying the averaging perturbation method, analytic equation has been derived to describe the steady state behavior of the system in various condition of the response. A simple parametric study verified the applicability of the analytic results.

The analysis has been done for a continuous (modeled by five nonlinear polynomial functions) and a piecewise linear model. Applying the averaging method to the continuous saturating function needed a careful analysis in every different step. The derived equations are cumbersome, long, complicated, and hard to work with. The analytic equation for describing the steady state behavior of the system has also been derived using a simpler model of piecewise linear saturating stiffness. The investigation has shown that the piecewise linear model generates much simpler analytic results, with reasonably close results. Therefore, the corresponding equations may be utilized for further investigation on saturating stiffness.
